

# Controllable Clickbait Text Generation

Dusan Svilarkovic, Dominik Stambach, Afra Amini, Elliott Ash  
ETH Zürich

## 1 Introduction

In the previous 5 years, thanks to the development of attention-based transformers (Vaswani et al., 2017) and its encoder (Devlin et al., 2018), decoder (Radford et al., 2019) and encoder-decoder variations (Lewis et al., 2019; Zhang et al., 2019), NLP has become a rapidly developing field, with a lot of computational power spent on pre-training multi-billion parameter models, currently only being able to be trained with the resources held by the private companies, and only recently by the public organization created by the open initiatives (Big Science, 2021). Due to computational capability requirements, the majority of the research has been focused on "tweaking" the currently existing state-of-the-art models. Model "tweaking" has become a challenge to overcome in controlled, topic-based text generation settings in selected approaches: CTRL (Keskar et al., 2019) Fudge (Yang and Klein, 2021) and PPLM (Dathathri et al., 2019).

Although transformer architectures have been capable of generating text through conditioned attribute decoding with previously mentioned approaches (CTRL (Keskar et al., 2019), Fudge (Yang and Klein, 2021), PPLM (Dathathri et al., 2019)), it was shown to be working with changing performance on explicit attributes. So far, no one has attempted yet to understand how to gradually increase attribute grade while generating text. Moreover, there have been attempts to conditionally, based on meta-attributes generate text for the newspaper articles, such as in Grover (Zellers et al., 2019), and while it has given excellent results and has proven to be able to create humanly-reasonable text, it still had a structure constraint and had no control over how conditioned meta-attribute might appear in the text.

Inspired by the previous conditioned approaches to generating fake news articles (Zellers et al., 2019), and their worries that their and existing

models might be capable of generating synthetic articles, we are proposing to create a controllable, attribute-based conditioned model for generating text based on the particular attribute. In our approach, we are generating clickbait titles, conditioned on the news article content, based on the "clickbait" grade of our classifier, and explore how this can be controlled through hyperparameter search. Moreover, unlike PPLM (Dathathri et al., 2019) and Fudge (Yang and Klein, 2021), which are using no-context, decoder-based GPT-2 (Radford et al., 2019), in our case, for generating news article titles, we use news article content and encoder-decoder based transformers (Zhang et al., 2019), (Beltagy et al., 2020) to generate titles.

## 2 Theoretical background

If we use probabilistic terminology, our goal is to create controllable, on-attribute conditioned text generation model  $P(X|a, X')$ , where  $X$  is a natural language sequence (news article title),  $a$  is an attribute, in our case "clickbaitiness", and  $X'$  is another natural language sequence (news article content). To create that model, we need a large language model  $P(X|X')$  and an on-attribute trained classifier  $P(X|a, X')$ . By using the unnormalized Bayes rule, we create a conditional text-to-title generator

$$P(X|a, X') = P(a|X, X') \times P(X|X').$$

For using this model, only on-attribute classifier needs to be trained.

## 3 Data and Summary Statistics

For training on-attribute classifier, we use Webis dataset (Potthast et al., 2018), a clickbait dataset, containing a single score label from 0 to 1 by a step of 0.33 for the how "clickbaity" a title is. Important attributes per sample are title, article content, and clickbait label. Dataset has 38,517 samples separated into the train, validation, and test datasets.

The clickbait truth label is binary values (0 for no-clickbait, 1 for clickbait). Webis dataset was created with the help of 5 MTurk workers, for each article giving a grade on a 4 values scale from 0 to 1 by 0.33 step (not-clickbait (0.0), slightly clickbait (0.33), considerably clickbait (0.66), heavily clickbait (1.0)), and the binary truth label was given from the mean and rounding an average grade. In total, 9,276 posts are clickbait. In figure 1, we are showing a screenshot of a comparison of various previously existing datasets. Usage of previously created datasets was abandoned, due to the lack of meta-attributes in those datasets and the possibility of overlapping news articles and data leakage in train/val/test splits with Webis dataset.

Publication	Genre	Teaser	Acquisition	Annotation (Scale, People, n)	Articles	Size
Agrawal (2016)	News	Headline	Gatekeeper-based	Binary 3 0.84	No	2,388
Potthast et al. (2016)	News	Tweet	Importance-based	Binary 3 0.35	Yes	2,992
Biyani et al. (2016)	News	Headline	Reputation-based?	Binary ? ?	?	4,073
Chakraborty et al. (2016)	News	Headline	Reputation-based	Binary 3 0.79	No	15,000
Rony et al. (2017)	News	Headline	Reputation-based	Binary 3 0.79?	No	32,000
<b>Webis-Clickbait-17</b>	News	Tweet	Importance-based	Graded 5 0.36	Yes	38,517

Table 1: Overview of clickbait corpora. All are in English; question marks (?) indicate lack of clarity.

Figure 1: A dataset table taken from Webis paper (Potthast et al., 2018). It shows how Webis-clickbait is the largest clickbait title dataset so far, and contains the largest scale range compared to the other datasets.

Furthermore, we also provide dataset content in figure 2, which shows the frequency of clickbait grades among the different publishers, showing that for example, BuzzFeed and Breitbart’s news has the highest clickbait content out of all publishers, while New York Times and Guardian are more on the opposite side of the clickbaitness spectrum.

Figure 2: A dataset content per publisher and by clickbait grade. Taken from Webis paper (Potthast et al., 2018)

For further comparison of per grade scale title contents, we have also created word clouds for each grading scale and they are shown on a figure 3. As you can see, clickbaity titles contain some phrases like "you need to know" or "these are the

# examples", meaning that there exist specific patterns in the title creation that can attract the readers, and that it is appearing in our dataset. For table-based visualization of 3-grams, please check out the Appendix A.

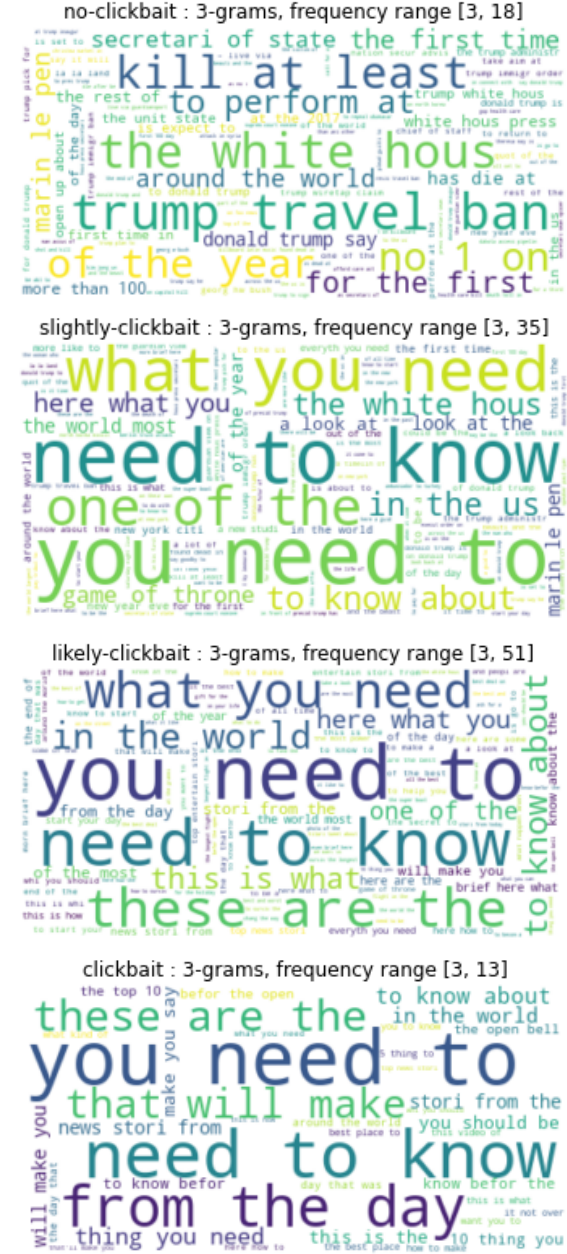

Figure 3: 3-gram wordcloud content of each clickbait scaling grade (0.0 for no-clickbait, 0.33, for slightly-clickbait, 0.66 for likely-clickbait, 1.0 for clickbait)

## 4 Methods

In order to adequately steer the text generation towards our attribute  $a$ , first we need a good clickbait classifier  $P(X|a, X')$ . For that, encoder based models BERT(Devlin et al., 2018), RoBERTa (Liu

et al., 2019) and MPNet (Song et al., 2020) were taken into consideration.

For steering our clickbait title generation, we have considered and reimplemented two previously existing models:

- **PPLM** (Dathathri et al., 2019) which is using gradient ascent on text generation model  $P(X|X')$  to steer model towards classifier’s output score  $P(a|X, X')$ .
- **Fudge** (Yang and Klein, 2021), which is using text generator’s  $P(X|X')$  decoder’s outputs and multiplying them with classifier’s output scores  $P(a|X, X')$  to steer text generation towards "clickbaitiness" attribute.

In both models, reimplementation included switching **text-generation** from GPT-2 (Radford et al., 2019) model to context-based Pegasus model (Zhang et al., 2019).

Both these models have already done this for generating text based on the attribute classifier, but none of them have ever done generating according to tunable attribute parameter in continuous space, i.e. instead of using classes 0 and 1 for steering, we use the whole space  $[0, 1]$ .

## 5 Results

### 5.1 Clickbait Classifier

As we mentioned above, the state of the art encoder-based models are used for classification based on the text title as the input on the above mentioned Webis dataset (Potthast et al., 2018). Since these models are pre-trained, they already contain some context on how certain words are correlated, but need the fine-tuning for the specific task to give us reasonable results. Fine-tuning is done for 6 epochs and by training it on the binary objective ("clickbait" and "no-clickbait") using binary cross entropy loss. In our case, the best model appeared

to be MPNet (Song et al., 2020). Result we get is compared with the Webis 2017 leaderboard in a table 1.

Although our model doesn’t achieve the best result in any of the metrics, in total it is one of the top metric results among other classifiers existing on the leaderboard. Therefore, we assume our classifier is good enough to be used for steering text generation in the next step.

### 5.2 Clickbait text generation

Our text generation works by using large language models in the few-shot setting, fine-tuning our text generator only on an epoch, and conditioning it on a trained classifier. Since our goal is to generate clickbait titles according to the input news article, we are also using a clickbait classifier from the previous step to see how well our title generator works. In the tables 2 and 3, we are showing what titles on news articles containing Kim Jong Un and Elon Musk (separately) look like. We see a couple of examples of how titles look in the original form (in the left column), and when it is being generated by our model (on the right column). Since sometimes our model is not able to generate clickbaity titles as we expect, we are also giving examples where the original titles were clickbait/non-clickbait, but the generated one was non-clickbait according to our clickbait classifier. Besides these two named entities, in the appendix A, we are also providing generated titles on articles containing Barack Obama, Hillary Clinton, combined Macron/Le Pen, Kanye West, the Republican Party, and Democratic Party.

An important part of our work also includes exploring how well our text generation model works for the different clickbait score ranges between  $[0, 1]$ . To get those title ranges based on the clickbait score, we also had to somehow tune our models to work properly with different hyperparameter

Team name	F1 score	Precision	Recall	Accuracy
<b>Our</b>	<b>0.678 (2nd)</b>	<b>0.707 (3rd)</b>	<b>0.65(2nd)</b>	<b>0.853 (2nd)</b>

settings and correlate them with clickbait scores, for both PPLM (Dathathri et al., 2019) and Fudge

(Yang and Klein, 2021) approach. To explore that, we used **conditional lambda** in Fudge approach (Yang and Klein, 2021), and **stepsize** in PPLM approach (Dathathri et al., 2019), which were also recommended by respective authors to tune for steering towards target attributes. The results are shown in the figure 4 for both approaches. As it can be seen, with increasing hyperparameter intensity, both approaches show increasing clickbait scores overall. In the case of a PPLM approach, (Dathathri et al., 2019), this growth is going with a more fine increase.

Figure 4: Clickbait score changes with the hyperparameter tuning. Each figure compares generated title scores on a clickbait classifier against the hyperparameter change. The separation between clickbait and non-clickbait titles is shown for the test samples’ ground truth clickbait values. There are two horizontal lines on each figure to show the original title score as estimated by our clickbait classifier. For both models, we see the correlation of the relevant hyperparameter with an overall clickbait score grade per subset of a dataset.

On the other hand, while this increase indeed shows continuous growth of clickbaitness of generated titles, one issue that arises is the consistency of the generated titles with the news articles it is supposed to target. In figure 5, we compare rouge scores of generated titles vs lead-3 baseline (where lead-3 means the first three sentences from each

news article). We see that through increased hyperparameter, while clickbaitness increases, its rouge score also drops. While this could be seen as a good thing, given that the point of a clickbait title is to be far from truthful content in the original article content, in our case it also means that generated titles can look incoherent in both syntax and semantics. This is something that should be a focus of future work and that more fine-tuning is needed for text generation to generate human-readable clickbait titles

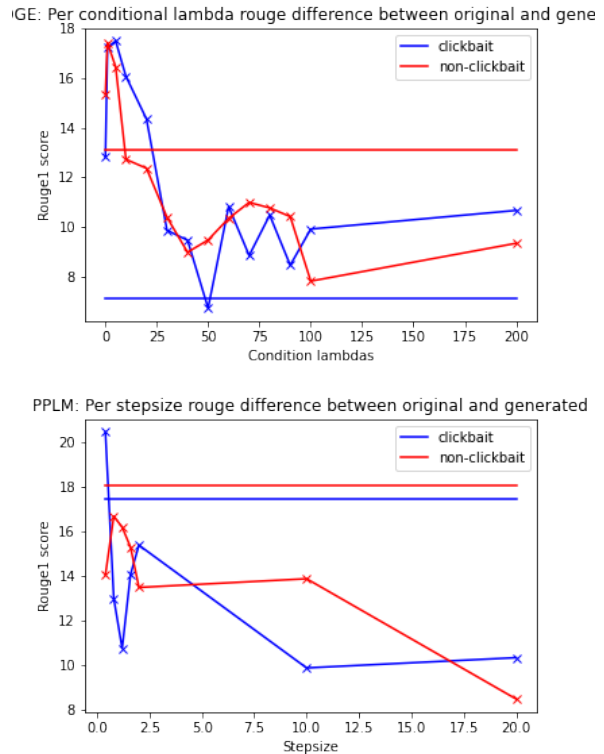

Figure 5: Rouge score change with the hyperparameter tuning. For both models there is a rouge score drop in coherency of the generated titles when compared to the lead-3 baseline. Horizontal lines are rouge scores of ground truth original titles vs lead-3 baseline. Lead-3 means first three sentences of each news article.

## 6 Conclusion

We have shown how our methods act when tuning hyperparameters, and how it affects final classifier’s outputs. There are two major approaches to be used for further improvements. The first one is training classifiers in a different manner compared to our approach. Since we train our classifier on a binary classification task, there is a firm reason to claim that this type of approach is not good enough for fine attribute-tuning to a  $[0, 1]$

range as we did, and that it might steer too much towards attribute-preferred tokens while text generating. Another way to consider would be as is done in Fudge (Yang and Klein, 2021), where they learn classifiers on subsequences to predict titles, which in the token-per-token approach could work better towards steering the attribute scores we are looking for (which they also do, but not towards continuous attribute scores, but only binary). The second one would be instead of doing a grid search over relevant hyperparameters in Fudge (Yang and Klein, 2021) and PPLM (Dathathri et al., 2019), we instead used some more sophisticated hyperparameter searches, such as Bayesian optimization or meta-learning algorithms for adequately setting up classifiers to give different results for different current title lengths.
